

# Logistic Regression: Complete Formula Term Reference

## Overview

This document summarizes all the key formulas used in Logistic Regression, along with explanations for each symbol, term name, and their role in the model. It is structured to help with manual implementation and understanding.

## Step-by-Step Summary

**Step 1: Linear Combination (Logit)** Computes the raw score using feature values and learned parameters.

$$z = w^T x + b$$

| Symbol  | Symbol Name       | Term Name            | What It Does                                   |
|---------|-------------------|----------------------|------------------------------------------------|
| $z$     | $z$               | Logit / Linear Score | Raw score before activation (input to sigmoid) |
| $w$     | $w$               | Weight Vector        | Parameters that assign importance to features  |
| $x$     | $x$               | Feature Vector       | Input data                                     |
| $b$     | $b$               | Bias / Intercept     | Adjusts decision boundary                      |
| $w^T x$ | $w$ transpose $x$ | Dot Product          | Weighted sum of features                       |

**Step 2: Sigmoid Function** Converts raw score  $z$  into a probability between 0 and 1.

$$\hat{y} = \sigma(z) = \frac{1}{1 + e^{-z}}$$

| Symbol      | Symbol Name  | Term Name             | What It Does                         |
|-------------|--------------|-----------------------|--------------------------------------|
| $\hat{y}$   | y-hat        | Predicted Probability | Model output: probability of class 1 |
| $\sigma(z)$ | sigma of $z$ | Sigmoid Function      | Maps raw score to probability space  |
| $z$         | $z$          | Logit                 | Input to sigmoid function            |
| $e$         | $e$          | Euler's Number        | Constant for natural exponentiation  |

**Step 3: Loss Function (Binary Cross-Entropy)** Measures error between predicted probability and true label.

$$\mathcal{L}(\hat{y}, y) = -[y \cdot \log(\hat{y}) + (1 - y) \cdot \log(1 - \hat{y})]$$

| Symbol          | Symbol Name   | Term Name             | What It Does                        |
|-----------------|---------------|-----------------------|-------------------------------------|
| $\mathcal{L}$   | $\mathcal{L}$ | Loss Function         | Quantifies error for one prediction |
| $y$             | $y$           | True Label            | Actual class label (0 or 1)         |
| $\hat{y}$       | y-hat         | Predicted Probability | Model output                        |
| $\log(\hat{y})$ | log y-hat     | Log-Likelihood        | Penalizes incorrect predictions     |

---

**Step 4: Cost Function (Mean Loss)** Averages loss over the entire dataset.

$$J(w, b) = \frac{1}{m} \sum_{i=1}^m \mathcal{L}(\hat{y}^{(i)}, y^{(i)})$$

| Symbol                                | Symbol Name | Term Name         | What It Does               |
|---------------------------------------|-------------|-------------------|----------------------------|
| $J(w, b)$                             | J           | Cost Function     | Measures total model error |
| $m$                                   | m           | Number of Samples | Size of dataset            |
| $\sum$                                | summation   | Total Loss        | Adds up individual losses  |
| $\mathcal{L}(\hat{y}^{(i)}, y^{(i)})$ | Loss i      | Per-sample Loss   | Loss for each example      |

**Step 5: Gradient Computation** Computes direction to update weights and bias to reduce loss.

$$\frac{\partial J}{\partial w} = \frac{1}{m} \sum_{i=1}^m (\hat{y}^{(i)} - y^{(i)}) x^{(i)} \quad \frac{\partial J}{\partial b} = \frac{1}{m} \sum_{i=1}^m (\hat{y}^{(i)} - y^{(i)})$$

| Symbol                          | Symbol Name      | Term Name          | What It Does                            |
|---------------------------------|------------------|--------------------|-----------------------------------------|
| $\frac{\partial J}{\partial w}$ | dJ/dw            | Gradient (Weights) | Shows how to change each weight         |
| $\frac{\partial J}{\partial b}$ | dJ/db            | Gradient (Bias)    | Shows how to change bias                |
| $(\hat{y}^{(i)} - y^{(i)})$     | prediction error | Residual           | Difference between prediction and truth |
| $x^{(i)}$                       | x-i              | Feature Vector     | Input data for sample i                 |

**Step 6: Gradient Descent Update Rule** Updates parameters using gradients and learning rate.

$$w := w - \alpha \cdot \frac{\partial J}{\partial w} \quad b := b - \alpha \cdot \frac{\partial J}{\partial b}$$

| Symbol                                                         | Symbol Name | Term Name        | What It Does                  |
|----------------------------------------------------------------|-------------|------------------|-------------------------------|
| $w, b$                                                         | parameters  | Weights and Bias | Model parameters to optimize  |
| $\alpha$                                                       | alpha       | Learning Rate    | Controls update size per step |
| $:=$                                                           | assignment  | Update Operator  | Applies parameter update      |
| $\frac{\partial J}{\partial w}, \frac{\partial J}{\partial b}$ | gradients   | Slopes           | Direction of steepest descent |

**Step 7: Final Prediction Rule** Converts probability into binary class label.

$$\text{predict} = \begin{cases} 1 & \text{if } \hat{y} \geq 0.5 \\ 0 & \text{otherwise} \end{cases}$$

| Symbol    | Symbol Name | Term Name             | What It Does                             |
|-----------|-------------|-----------------------|------------------------------------------|
| $\hat{y}$ | y-hat       | Predicted Probability | Output probability from model            |
| Threshold | threshold   | Decision Cutoff       | Default is 0.5 for binary classification |
| 0 or 1    | class label | Final Prediction      | Assigned class based on threshold        |
